Modern computer architectures designed with high-performance

microprocessors offer tremendous potential gains in performance over previous designs. Yet their very complexity makes it increasingly difficult to produce efficient code and to realize their full potential. This landmark text from two leaders in the

field focuses on the pivotal role that compilers can play in addressing this critical issue. The basis for all the methods presented in this book is data dependence, a fundamental compiler analysis tool for optimizing programs on high-performance

architectures. The text provides a broad introduction to data dependence, to the many transformation strategies it supports, and to its applications to important optimization problems such as parallelization,

demonstrate the importance and wide applicability of dependence-based compiler optimizations and give the compiler writer the basics

This book brings a unique treatment of compiler design

to the professional who seeks an in-depth examination of a real-world compiler. Chris Fraser of AT & T Bell Laboratories and David Hanson of Princeton University codeveloped lcc, the retargetable ANSI C compiler that is the focus of

this book. They provide complete source code for lcc; a target-independent front end and three target-dependent back ends are packaged as a single program designed to run on three different platforms. Rather than transfer code

into a text file, the book and the compiler itself are generated from a single source to ensure accuracy.

semantic analysis, specification mechanisms for these tasks from the theory of formal languages, and methods for automatic generation based on the theory of

structure, i.e., a division into a set of modules, which transform an input program into a sequence of steps in a machine program, and they then describe the interfaces between

Finally, the structures of real translators are outlined. The book contains the necessary theory and advice for implementation.
